Premise: I analyzed lyrics written by my favorite seven artists, taken from their first and most recent albums/EPs. I want to find unknown clusters of the songs based on similarities in energy, positivity, and introspectiveness, according to the following scale:

Score	Energy	Positivity	Introspectiveness
0	Slow, whispery	Hopelessness	Singular external
1	Slow acoustic	Anger	Group external
2	Slow rock ballad	Annoyance	Society
3	Moderate pop	Bittersweet	Social norms
4	Classic rock	Hopeful	Group internal
5	Fast rock	Redemption	Couple internal
6	Fast punk	Love	Habit analysis
7	Fast metal	Elation	Fully internal

Once I have the clusters, I want to describe each cluster with a profile (an average or centroid with scores for each category), and note the distribution of each artists' songs in each cluster. Then, I will interpret artist profiles from that data.

Implementation Plan: First, I want to run the K-means algorithm for K in {7, 8, 9, 10, 11, 12, 13, 14), to see which model best fits the data (minimizes the K-means objective function, which is based on the distances from the datapoints to the assigned centroids).

Once I find the optimal value of K, I want to analyze the distribution of each artists' songs among the centroids, to make distinctions between the styles of the different artists.
